## Consider this dataset

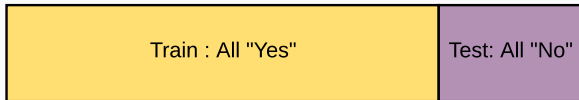

First 80 examples are of class “Yes”

Remaining 20 examples are of class “No”.

Serial Number	...	Class
1		Yes
2		Yes
3		Yes
.		.
.		.
80		Yes
81		No
.		.
.		.
100		No

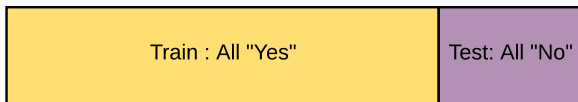

## Consider this dataset

While using an 80-20 train-test split, we will get the distribution shown below

## Consider this dataset

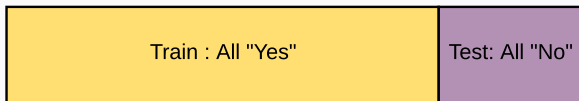

While using an 80-20 train-test split, we will get the distribution shown below

Will we learn anything useful in this scenario?

## Consider this dataset

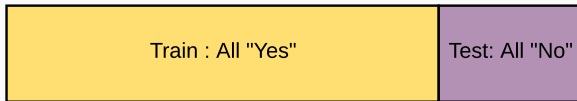

While using an 80-20 train-test split, we will get the distribution shown below

Will we learn anything useful in this scenario? *No :(*

## Consider this dataset

While using an 80-20 train-test split, we will get the distribution shown below

Will we learn anything useful in this scenario? *No :(*

**Solution:** Shuffle before learning

## Why shuffle for SGD?

We can fall into a loop!

SGD on point 1 :  $\theta_0 + 0.2, \theta_1 - 0.2$

SGD on point 2 :  $\theta_0 - 0.2, \theta_1 + 0.2$

Biased learning as point 2 follows point 1.
